# Mathematical Tools for Neural and Cognitive Science

Fall semester, 2021

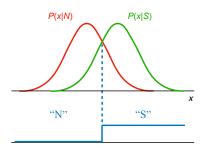

Section 5a:

# Statistical Decision Theory + Signal Detection Theory

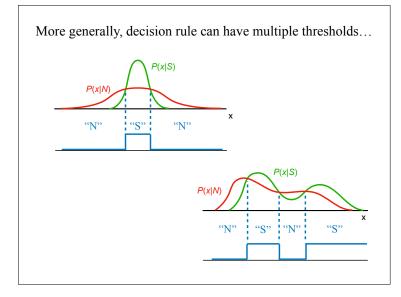

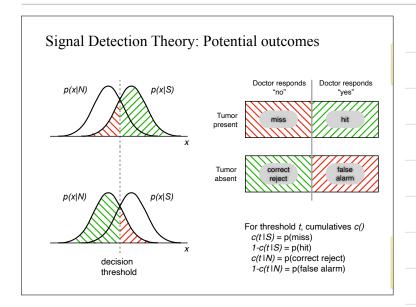

Tumor, or not?

# Signal Detection Theory (binary estimation)

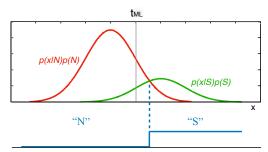

For equal-shape, unimodal, symmetric distributions, the ML decision rule is a *threshold* function.

## MAP decision rule?

MAP solution maximizes proportion of correct answers, taking prior probability into account.

Compared to ML threshold, the MAP threshold moves *away* from higher-probability option.

# Bayes decision rule?

Incorporate values for the four possible outcomes:

#### Payoff Matrix

Response

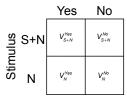

Yes No

Stimulus

S+N	$V_{S+N}^{ m Yes}$	$V_{_{\mathcal{S}+N}}^{No}$
N	V <sub>N</sub> <sup>Yes</sup>	$V_{_{N}}^{_{NO}}$

# **Bayes Optimal Criterion**

#### Response

$$\begin{split} \mathbb{E}(Yes \mid x) &= V_{S+N}^{Yes} p(S+N \mid x) + V_{N}^{Yes} p(N \mid x) \\ \mathbb{E}(No \mid x) &= V_{S+N}^{No} p(S+N \mid x) + V_{N}^{No} p(N \mid x) \end{split}$$

Say yes if  $\mathbb{E}(Yes \mid x) \ge \mathbb{E}(No \mid x)$ 

# **Optimal Criterion**

$$\mathbb{E}(Yes\,|\,x) = V_{S+N}^{Yes} p(S+N\,|\,x) + V_N^{Yes} p(N\,|\,x)$$

$$\mathbb{E}(No\,|\,x) = V_{S+N}^{No}p(S+N\,|\,x) + V_N^{No}p(N\,|\,x)$$

Say yes if  $\mathbb{E}(Yes \mid x) \ge \mathbb{E}(No \mid x)$ 

Say yes if 
$$\frac{p(S+N \mid x)}{p(N \mid x)} \geq \frac{V_N^{No} - V_N^{Yes}}{V_{S+N}^{Yes} - V_{S+N}^{No}} = \frac{V(\operatorname{Correct} \mid N)}{V(\operatorname{Correct} \mid S+N)}$$

Posterior odds

# Apply Bayes' Rule

Posterior Likelihood Prior
$$p(S + N \mid x) = \frac{p(x \mid S + N)p(S + N)}{p(x)}$$
Nuisance normalizing term

$$p(N \mid x) = \frac{p(x \mid N)p(N)}{p(x)}$$
, hence

$$\frac{p(S+N\mid x)}{p(N\mid x)} = \left(\frac{p(x\mid S+N)}{p(x\mid N)}\right) \left(\frac{p(S+N)}{p(N)}\right)$$
Posterior odds

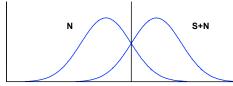

Likelihood ratio

# **Optimal Criterion**

Say yes if 
$$\frac{p(S+N \mid x)}{p(N \mid x)} \ge \frac{V(\text{Correct} \mid N)}{V(\text{Correct} \mid S+N)}$$

i.e., if 
$$\frac{p(x \mid S+N)}{p(x \mid N)} \ge \frac{p(N)}{p(S+N)} \frac{V(\text{Correct} \mid N)}{V(\text{Correct} \mid S+N)} = \beta$$

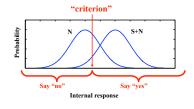

Example, if equal priors and equal payoffs, say yes if the likelihood ratio is greater than one:

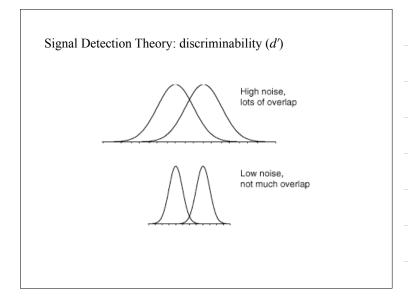

# Example applications of SDT

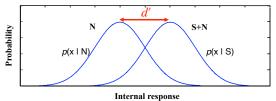

- Vision
- Detection (something vs. nothing)
- Discrimination (lower vs greater level of: intensity, contrast, depth, slant, size, frequency, loudness, ...
- Memory (internal response = trace strength = familiarity)
- Neurometric function/discrimination by neurons (internal response = spike count)

From experimental measurements, assuming human is optimal, can we determine the underlying distributions and criterion?

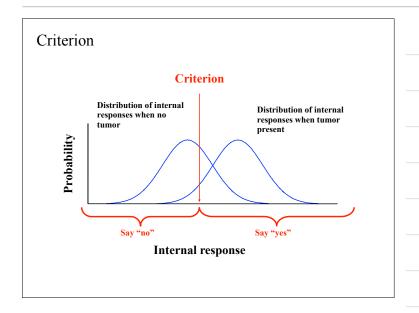

Internal response: probability of occurrence curves

 $d' = \frac{\text{"separation"}}{\text{"width"}}$ 

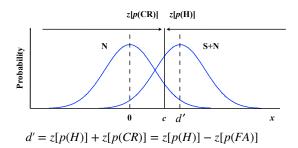

Discriminability ("d-prime") is the normalized separation between the two distributions

Error rate is a function of d'

### SDT: Gaussian case

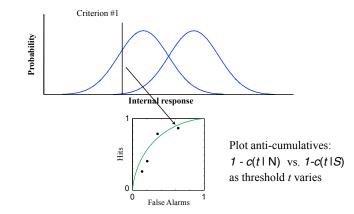

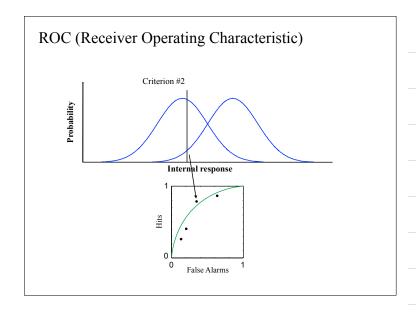

Hits = 50% False alarms = 16%

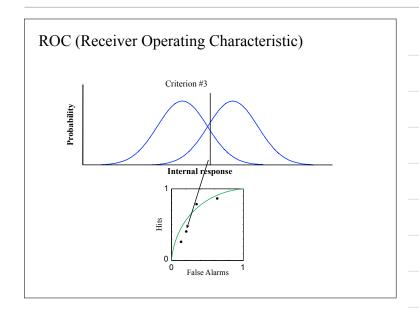

$$c = z[p(CR)] \qquad G(x; \mu, \sigma) = \frac{1}{\sqrt{2\pi\sigma}} e^{-(x-\mu)^2/2\sigma^2}$$

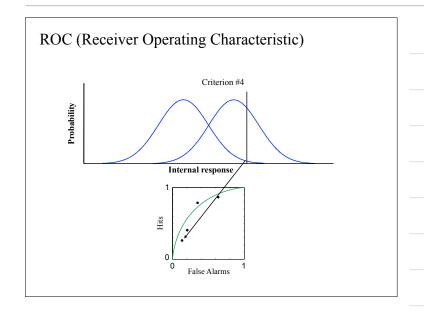

$$\beta = \frac{p(x = c \mid S + N)}{p(x = c \mid N)} = \frac{e^{-(c-d')^2/2}}{e^{-c^2/2}} \qquad (\text{Fix } \sigma = 1)$$

# ROC (Receiver Operating Characteristic)

# ROC (Receiver Operating Characteristic) $d' = 1 \text{ (lots of overlap)} \qquad d' = 3 \text{ (less overlap)}$ ROC curves $\frac{29}{\pm}_{0.5}$ False alarms

# Decision/classification in multiple dimensions

[on board: Area under curve = %correct in a 2AFC task]

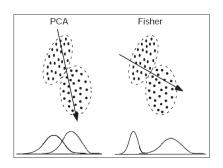

- Data-driven linear classifiers:
  - Prototype Classifier minimize distance to class mean
  - Fisher Linear Discriminant (FLD) maximize d'
  - Support Vector Machine (SVM) maximize margin
- Statistical:
  - ML/MAP/Bayes under a probabilistic model
  - e.g.: Gaussian, identity covariance (same as Prototype)
  - e.g.: Gaussian, equal covariance (same as FLD)
  - e.g.: Gaussian, general case (Quadratic Discriminator)
- Some Examples:
  - Visual gender classification
  - Neural population decoding

# Linear Classifier Find unit vector $\hat{w}$ ("discriminant") that best separates the distributions class A Decision boundary class B histogram of projected values $\hat{w} \cdot \vec{x}$

Simplest linear discriminant: the Prototype Classifier

$$\hat{w} = \frac{\vec{\mu}_A - \vec{\mu}_B}{\|\vec{\mu}_A - \vec{\mu}_B\|}$$

# Fisher Linear Discriminant

$$\max_{\hat{w}} \frac{\left[\hat{w}^T (\overrightarrow{u}_A - \overrightarrow{u}_B)\right]^2}{\left[\hat{w}^T C_A \hat{w} + \hat{w}^T C_B \hat{w}\right]}$$

(note: this is d' squared!)

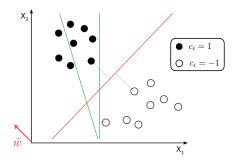

optimum:  $\hat{w} = C^{-1}(\overrightarrow{u}_A - \overrightarrow{u}_B)$ , where  $C = \frac{1}{2}(C_A + C_B)$ 

# Support Vector Machine (SVM)

(widely used in machine learning, but no closed form solution)

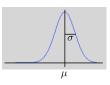

Maximize the "margin" (gap between data sets):

find largest m, and  $\{\hat{w}, b\}$  s.t.  $c_i(\hat{w}^T \vec{x}_i - b) \geq m, \quad \forall i$ 

### Reminder: Multi-D Gaussian densities

$$p(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

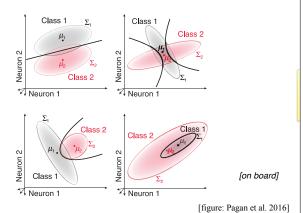

$$p(\vec{x}) = \frac{1}{\sqrt{(2\pi)^N |C|}} e^{-(\vec{x} - \vec{\mu})^T C^{-1} (\vec{x} - \vec{\mu})/2}$$

mean: [0.2, 0.8] cov: [1.0 -0.3; -0.3 0.4]

# ML (or MAP) classifier for two Gaussians

Decision boundary is *quadratic*, with four possible geometries:

# A perceptual example: Gender identification

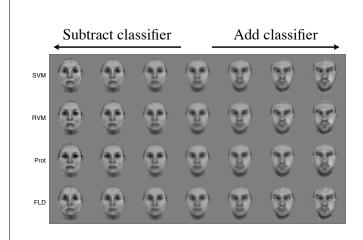

- •200 face images (100 male, 100 female)
- Adjusted for position, size, intensity/contrast
- •Labeled by 27 human subjects

[Graf & Wichmann, NIPS\*03]

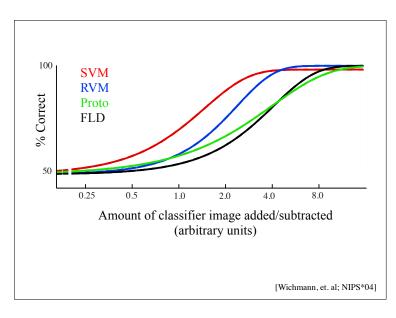

# Linear classifiers SVM RVM Prot FLD W Four linear classifiers trained on subject data

# Model validation/testing

- Cross-validation: Subject responses [% correct, reaction time, confidence] are explained
  - very well by SVM
  - moderately well by RVM / FLD
  - not so well by Prot
- Curse of dimensionality strongly limits this result. A more direct test: Synthesize optimally discriminable faces...

[Wichmann, et. al; NIPS\*04]

#### Fisher Information

• Second-order expansion of the (expected) negative log likelihood:

$$I(s) = -\mathbb{E}\left[\frac{\partial^2 \log p(r|s)}{\partial s^2}\right]$$

- • Provides a bound on "precision" of unbiased estimators:  $\sigma^2(s) \geq \frac{1}{I(s)}$
- • Perceptually, provides a bound on discriminability: (Series et. al. 2009)  $D(s) \leq \sqrt{I(s)}$
- Examples: with mean stimulus response f(s)

Gaussian case:  $p(r|s) \sim \mathcal{N}(f(s), \sigma^2)$   $I(s) = [f'(s)]^2/\sigma^2$ 

Poisson case:  $p(r|s) \sim \text{Poiss}(f(s))$   $I(s) = [f'(s)]^2/f(s)$ 

### Example: Weber's law

$$D(s) \propto \frac{1}{s} \leq \sqrt{I(s)}$$

Assuming  $I(s) \propto \frac{1}{s^2}$  what internal representation explains this? Many!

additive Gaussian noise, with mean  $f(s) = \log(s) + c$ 

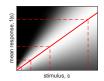

entirely due to response mean (Fechner, 1860)

Poisson noise, with mean

$$f(s) = [\log(s) + c]^2$$

discrete representation, depends on both mean and variance

multiplicative Gaussian noise, with mean

entirely due to response variance
